Installing sudo & configuration of user and groups

sudo is a [program](#) for [Unix-like](#) computer [operating systems](#) that enables users to run programs with the security privileges of another user, by default the [superuser](#). It originally stood for "superuser do", as that was all it did, and it is its most common usage; however, the official Sudo project page lists it as "su 'do'".

Installing sudo

1. **Switch to root user:** First, we need to change to the root user to install sudo. Enter the following command:

```
su
```

When prompted, enter the root password you set during installation (in our example: `Ho1a42bcn`).

2. **Install sudo package:** Once you're logged in as root, run the following command:

```
apt install sudo
```

This command tells the package manager to install the required packages for sudo. Press `y` when prompted to confirm the installation.

3. **Reboot the system:** We must reboot the machine so the changes can be applied. Use the following command:

```
sudo reboot
```

4. **Verify installation:** Once the machine has rebooted, enter the encryption password and log in again. To check if sudo has been installed correctly, switch to the root user:

```
su
```

Then verify the sudo installation with:

```
sudo -V
```

This command will display the sudo version and configuration details if the installation was successful.
